

# Expression Layer — v1.0

Four custom SEL expressions built for TorBox · AIOStreams

Status: Trial — Core Nexus Stream v2.7.10 · June 2026

This document describes the four original SEL expressions developed under the Core Builds project. They are designed to layer on top of the Tam-Taro expression stack and address gaps not covered by the standard AIOStreams ESE/PSE/ISE suite. Each expression is independently toggleable.

## 01 REPACK / PROPER Passthrough

ISE — Included Stream Expression

**Purpose** Ensures REPACK and PROPER releases always surface at the head of results, ahead of the excluded/limited filter pipeline. Without this, a REPACK can be silently suppressed by downstream ESEs (e.g. the per-addon flood guard or final limit) before the user ever sees it.

**How it works** Checks whether any non-library/non-SeaDex stream carries the 'repack' or 'proper' keyword. If at least one exists, those streams are passed through with their excluded and limit flags cleared — bypassing downstream pruning. If none exist, the ISE returns an empty array and has no effect.

**When to use** *Always enabled. No configuration needed.*

### SEL Expression

```
/*REPACK/PROPER Passthrough*/ count(keyword(negate(merge(library(streams), seadex(streams)), streams), 'all', 'repack', 'proper'))>0?passthrough(keyword(negate(merge(library(streams), seadex(streams)), streams), 'all', 'repack', 'proper'), 'excluded', 'limit'):[]
```

## 02 Per-Addon Flood Guard

ESE — Excluded Stream  
Expression

|                     |                                                                                                                                                                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>      | Prevents any single scraper from flooding the result list with low-quality or duplicate cached results. Scrapers like Meteor and Comet can return 20+ results for a single query; without a cap, they drown out higher-quality results from other addons. |
| <b>How it works</b> | For each scraper, takes the cached non-library/non-SeaDex streams from that addon and slices to a per-addon cap. Streams beyond the cap are excluded. Library and SeaDex streams are exempted entirely — they are never pruned by this guard.             |
| <b>Caps</b>         | Meteor: $\leq 5$ · Comet RD: $\leq 5$ · MediaFusion: $\leq 4$ · Torrent Galaxy: $\leq 3$ · EZTV: $\leq 3$ · Knaben: $\leq 3$ · HdHub: $\leq 3$                                                                                                            |
| <b>When to use</b>  | <i>Always enabled. Adjust caps per-addon in the expression if your addon stack differs.</i>                                                                                                                                                               |

### SEL Expression

```
/*Per-Addon Flood Guard*/ merge(slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'Meteor'), 5), slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'Comet RD'), 5), slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'MediaFusion'), 4), slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'Torrent Galaxy'), 3), slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'EZTV'), 3), slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'Knaben'), 3), slice(addon(negate(merge(library(streams), seadex(streams)), cached(streams)), 'HdHub'), 3))
```

## 03 Usenet Propagation Guard

ESE — Excluded Stream  
Expression

|                     |                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>      | Suppresses usenet/stremio-usenet results that are still within the first 5 minutes of propagation — but only when fully propagated NZBs already exist. Early-propagation grabs are often incomplete or corrupt; this guard ensures the player always receives a complete NZB.                               |
| <b>How it works</b> | Checks if any usenet results older than ~5 minutes (0.083 hours) exist. If they do, it excludes all usenet results younger than that threshold. If no propagated results exist yet (brand-new release), the guard does nothing — the young results are allowed through so the user isn't left empty-handed. |
| <b>When to use</b>  | <i>Always enabled. Most effective on Usenet-heavy configurations (TorBox with Newznab).</i>                                                                                                                                                                                                                 |

### SEL Expression

```
/*Usenet Propagation Guard*/ count(negate(age(type(streams, 'usenet', 'stremio-usenet'), 0, '0.083'), type(streams, 'usenet', 'stremio-usenet')) > 0 ? age(type(streams, 'usenet', 'stremio-usenet'), 0, '0.083') : [])
```

## 04 Codec Efficiency Booster

PSE — Preferred Stream Expression

|                     |                                                                                                                                                                                                                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>      | Surfaces HEVC and AV1 encodes ahead of AVC equivalents within the same quality and resolution tier. HEVC/AV1 deliver equivalent perceptual quality at 30–50% lower bitrate — important for bandwidth-constrained connections and long-form series where storage efficiency matters.                                   |
| <b>How it works</b> | Applies to 1080p and 720p cached streams (excluding library/SeaDex). Across Bluray REMUX and WEB-DL/WEBRip quality tiers, any stream encoded in HEVC or AV1 is ranked ahead of AVC. Scope is deliberately limited to 1080p/720p — 4K REMUX streams are not touched since bitrate is part of the quality signal there. |
| <b>When to use</b>  | <i>Always enabled. Has no effect if all cached streams are AVC (falls through gracefully).</i>                                                                                                                                                                                                                        |

### SEL Expression

```
/*Codec Efficiency Booster*/ merge(encode(resolution(quality(negate(merge(library(streams), seadex(streams)), cached(streams)), 'Bluray REMUX'), '1080p'), 'HEVC', 'AV1'), encode(resolution(quality(negate(merge(library(streams), seadex(streams)), cached(streams)), 'WEB-DL', 'WEBRip'), '1080p'), 'HEVC', 'AV1'), encode(resolution(quality(negate(merge(library(streams), seadex(streams)), cached(streams)), 'Bluray REMUX'), '720p'), 'HEVC', 'AV1'), encode(resolution(quality(negate(merge(library(streams), seadex(streams)), cached(streams)), 'WEB-DL', 'WEBRip'), '720p'), 'HEVC', 'AV1'))
```

*These expressions are designed to complement the Tam-Taro SEL stack, not replace it. They operate in the Core Builds layer on top of the standard Tam-Taro ESEs/ISEs/PSEs. All four are independently toggleable — disable any that conflict with your setup.*
